Permutation self-consistency

Cancelling positional bias in a single pairwise judge call.

Special case: if A and B are byte-identical, the forward and backward prompts are the literal same string, so a provider that honors its seed parameter must return the same raw value v for both, giving $W[A, B] = (v + (1 - v))/2 = 0.5$ by arithmetic identity, for *any* v. Section 6.1 reports a live case where this failed – direct evidence the seed guarantee was not honored – which is why identical-text pairs skip the judge call and are assigned 0.5 directly.
